Dematerialization and its Role in Shaping Sustainable Futures

BHARATH P.[1] **AND JYOTIRMOY BANERJEE**[2]

ABSTRACT

Amidst the pressing global environmental challenges—such as climate change, biodiversity loss, and pollution—researchers are advocating for the concept of dematerialization. This strategy focuses on reducing consumption of materials and improving resource efficiency to minimize environmental impacts. The significant capital needed, extended lead-times, and the political implications associated with new resource exploitation underscore the importance of long-term evaluations of resource needs in strategic policy-making. Dematerialization is primarily driven by ongoing advancements in technology. However, this progress can be undermined by the rebound effect, where increased usage arises from higher value or reduced costs attributable to these technological improvements. A critical question to explore is the degree to which enhancements in technological performance can mitigate and are currently countering the persistent rise in economic consumption. The consensus surrounding the need for sustainability to drive economic growth alongside social progress and environmental stewardship is clear. Despite progress, there remains an ongoing conversation about the practical considerations related to forthcoming products, materials, and technologies. The real challenge is establishing sustainability as a foundation that drives innovation throughout various processes, technologies, business models, and management systems.

The purpose of this paper is to examine the fundamental principles of dematerialization through a review of current literature and relevant case studies, while also considering its relationship with the Sustainable Development Goals (SDGs) and its importance across various sectors in today's society. Additionally, the paper will investigate how several innovations and policies reflect the principles of dematerialization and how this approach contributes to achieving the SDGs. Findings suggest that dematerialization is a vital pathway for the future of humanity. Many developed nations and some emerging economies are currently promoting this initiative. This article examines long-term trends regarding the intensity of energy and material usage, correlating them with the theory of dematerialization. The discussion revolves around key factors influencing these trends, such as shifts in the structure of final demand, advancements in material efficiency, and the adoption of alternative materials. Additionally, the article points out the limitations of the

dematerialization theory as a tool for empirical forecasting and evaluates its applicability within the context of resource policy. However, it is crucial to acknowledge that the full benefits may not be immediately visible, and increased technological and political support will be essential globally to enhance its advancement and effectiveness.

***Keywords**: Dematerialization, Sustainability, policy-making, Energy Sector, Green Hydrogen Mission and National Mission for Enhanced Energy Efficiency (NMEEE).*

I. INTRODUCTION

The environmental consequences of global economic growth and development have ignited significant discussions within academic and policy circles. There are strong calls for a transition towards a "green economy," while others advocate for a fundamental reevaluation of the focus on economic expansion. Central to this debate is the dependence of both developing and industrialized countries on environmental resources, particularly regarding materials and energy. The idea that economic growth can be decoupled from environmental reliance suggests the potential for a considerable reduction in environmental impacts and a decrease in the threat of global ecological disasters.

Advocates for dematerialization often take a traditional engineering and economic viewpoint, providing robust evidence that it is possible to sustain current levels of well-being while significantly curtailing the consumption of natural resources. They typically frame dematerialization as an optimization challenge, asserting that strategic systems design and appropriate incentives can address it. However, this raises important questions: Can social systems be effectively optimized in this way, and who has the authority to implement such changes? Moreover, when one subsystem is optimized, does it not have unintended effects on others, potentially resulting in what is known as the rebound effect? To contribute to the existing body of literature, this research seeks to investigate the social science perspective on the conditions and implications of dematerialization through services and information technology.

II. DIRECTING FOCUS ON DEMATERIALIZATION

Dematerialization has emerged as a pivotal objective for achieving ecological sustainability in recent years. Various sectors and perspectives have propelled this emphasis on curbing the volume of materials circulating within the economy. A key factor is the increasing realization of the challenges associated with evaluating the relative impacts of different substances and interventions. Consequently, it has been posited that, given the existing uncertainties, it would be prudent to restrict anthropogenic material flows to a (politically defined) fraction of the

natural substance cycles.

In addition, certain types of waste are not inherently problematic, but rather become an issue due to their sheer volume, such as carbon dioxide (CO2). This particular waste cannot be effectively managed at the point of emission; the most practical approach is to reduce reliance on carbon-rich fuels. It is important to note that only a limited number of waste products can be adequately monitored and controlled at the emission source, typically those that originate from identifiable, stationary sources.

The concept of dematerialization offers a host of potential benefits, including environmental protection, equitable global resource distribution, enhanced business competitiveness, and the possibility of full employment. While these prospects are appealing, they may seem overly optimistic. Without delving into the complex debates regarding the adequacy of aggregate natural resource usage as an indicator of environmental strain, it is pertinent to highlight two additional challenges that warrant attention. Consequently, adopting a strategy that limits the intensity and extent of human activities can be viewed as a precautionary measure in response to prevailing uncertainties.

Economic activity inherently requires the utilization of natural resources, though the extent of this use can vary based on the structure and efficiency of economic processes. Many industrialized nations have implemented policies aimed at encouraging a decoupling of economic activity from resource consumption. This is often achieved by establishing targets to reduce the material intensity of economic operations. However, these targets tend to lead to a relative rather than an absolute decoupling between the economy and its material foundation. In less favorable scenarios, they may merely endorse continuous improvements in efficiency without impactful change. Therefore, it is crucial to analyze historical and current trends regarding material and energy dependencies in different economies. Additionally, it is important to make clear distinctions between the developmental paths of countries that are still in the process of industrialization and those that have already completed their industrial journey.

(A) How can services and IT play a role in promoting dematerialization?

Services play a crucial role in organizing markets to enhance the shared and efficient use of products, such as car-sharing initiatives. This model reduces the need for numerous products and allows for quicker implementation of efficiency improvements; for example, the total mileage of a vehicle can be utilized more effectively. Furthermore, customers benefit from access to a diverse array of products that can adapt to their evolving requirements, eliminating

the necessity for excessive options. Services offered on a professional level, such as car maintenance and washing, can also achieve greater resource efficiency compared to individual efforts. Additionally, this service-oriented approach can promote improved management of products at the end of their life cycle, including the recycling of used vehicles.

Services offer providers distinct economic incentives compared to traditional product sales. Instead of focusing on maximizing production and sales, service providers are motivated to minimize the costs associated with material products. This paradigm encourages them to extend the life cycle of rental goods, thereby enhancing sustainability. When services evolve to encompass operational aspects—known as results-oriented services—providers also gain the incentive to reduce operational expenses. An ideal service business model aggregates all life-cycle costs under the purview of the professional service provider. This approach addresses information asymmetries in market transactions, making energy and material costs more significant as they are consolidated within a single entity. Consequently, this model caters to customers by fulfilling their needs more effectively and efficiently.

(B) Research Questions and Goals

As macroeconomic material flow indicators for resource efficiency assessment continue to evolve, a critical analysis of mass-based indicators is necessary to uncover what they truly signify regarding the conservation and efficient utilization of natural resources. These indicators are not only of practical importance but also resonate on an instinctual and emotional level.

Our entire value-added chain hinges on the transformation of materials and substances. This process begins with the extraction of raw materials from the environment, followed by their transformation, and culminates in the release of emissions and waste back into our natural surroundings, thus impacting their condition. It's noteworthy that even sectors traditionally viewed as non-material, such as education, rely heavily on these material transformation processes. The infrastructure necessary for delivering these services—including roads, railways, heated buildings, and data centers—also depends on auxiliary materials and fuels, with a predominant reliance on fossil fuels. In summarizing these relationships, we can better understand the implications of our resource use and identify pathways toward more sustainable practices.

In light of the significant role that material flows play in our economy, can we consider a uniform reduction of material use by a factor of X as a foundational principle for achieving sustainability? Is it reasonable to expect a consistent decrease in environmental pressures and

a resolution to resource scarcity if we universally lower material consumption by this factor, as suggested by proponents of dematerialization? How dependable is the measurement of resource conservation achievements through dematerialization metrics quantified in kilograms, tonnes, and megatonnes? Furthermore, is there a meaningful connection between these metrics and the specific areas of environmental protection? Given the vast array of natural resources, to what extent do mass-based indicators truly reflect resource significance? Can they be effectively employed as control variables in policies designed to promote resource conservation and efficient utilization?

To effectively navigate the intricate dynamics of industrial system transitions within an interconnected industrial-socio-ecological framework, it's essential to adopt the appropriate methodologies and approaches. A significant portion of the research literature exploring concepts such as 'dematerialization,' 'decarbonization,' 'material efficiency,' 'circular economy,' and other related topics utilizes either quantitative or qualitative methods (see Table 1). These methods encompass various techniques, including life cycle assessment, material flow analysis, structural equation modeling, analytic hierarchy process, multi-criteria decision making, system dynamics, social network analysis, fuzzy set theory, and a range of multi or hybrid modeling strategies. Some studies integrate both quantitative and qualitative approaches, while others focus on a conceptual framework, conducting systematic literature reviews or employing descriptive, exploratory, and explanatory research, often incorporating case studies.

III. INDUSTRIAL SYSTEM TRANSITION INVOLVES DEMATERIALIZATION AND DECARBONIZATION

Dematerialization and decarbonization hinge on robust policy support, particularly due to the vital importance of technology push, technology transfer, and the financial flows that occur from developed to developing nations. Typically, foundational research and small-scale projects receive adequate backing through technology push initiatives. However, once a technology demonstrates its effectiveness on a smaller scale, it must be put to the test in real-world applications. At this stage, costs can soar significantly, while revenues may not increase correspondingly.

Governance, policies, and regulations play a critical role in the transition of industrial systems. Effective governance encompasses various dimensions, including transnational governance, technology push, market pull, technology transfer, financial flows, the establishment of a carbon price, and the development of carbon markets. Sustainability transitions are complex

processes that involve multiple, interdependent components, such as technologies, markets, infrastructures, policies, industry structures, and supply and distribution chains. These elements are often organized into stable regimes that can be understood in terms of technologies, institutions, and actors. Therefore, the significance of governance, policies, and regulation in this context cannot be overstated.

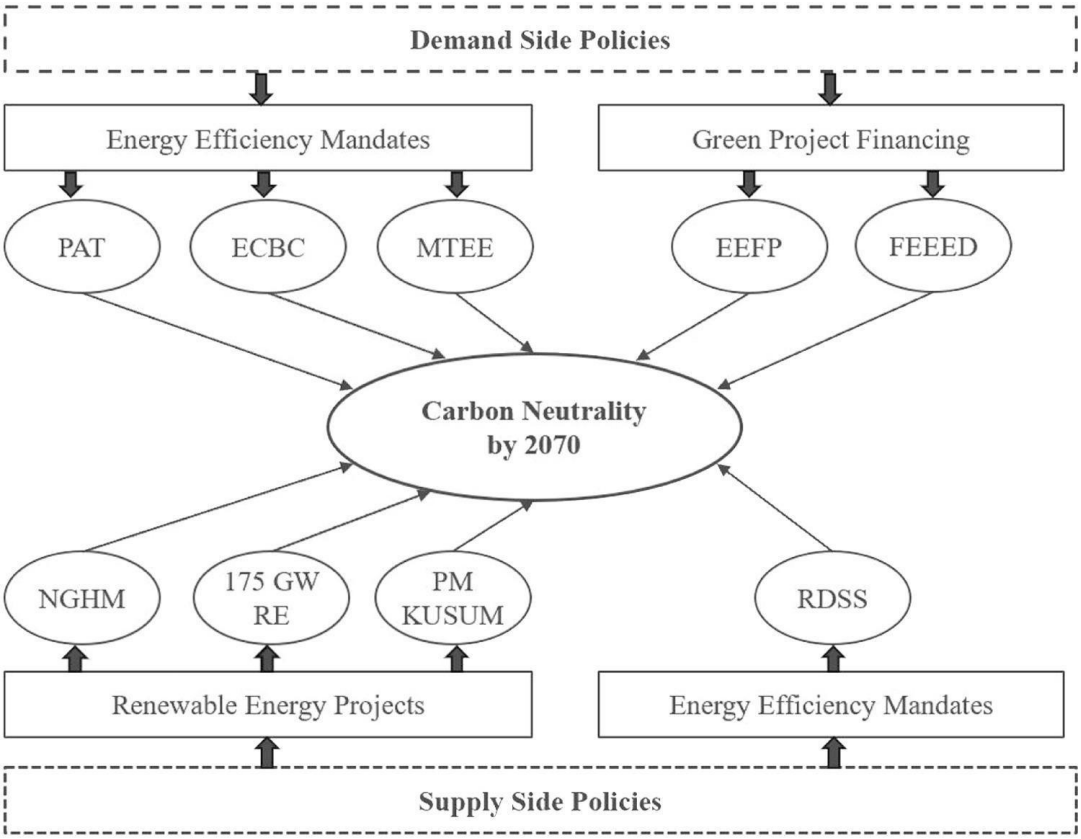
IV. CURRENT POLICIES IN THE ENERGY SECTOR

Energy policy plays a pivotal role in shaping a nation's energy independence and its position in the global economy. In India, the approach centers on diversifying energy sources, enhancing domestic production capabilities, and strengthening energy infrastructure. A key objective is to reduce dependence on foreign energy imports, which not only improves energy security but also mitigates vulnerabilities to market volatility. While challenges exist on the demand side, the supply-side issues include ineffective energy regulations, a reliance on foreign energy sources, and an overdependence on non-renewable fuels.

To tackle challenges on the demand side, the Government of India (GOI) launched the National Mission for Enhanced Energy Efficiency (NMEEE) in 2011, which encompasses four principal policies: the Perform, Achieve and Trade (PAT) mechanism, the Market Transformation for Energy Efficiency (MTEE), the Energy Efficiency Financing Platform (EEFP), and the Framework for Energy Efficient Economic Development (FEEED). These policies aim to encourage industries to achieve specific energy efficiency targets, facilitate the adoption of energy-efficient technologies, support financing for energy projects, and promote economic growth through enhanced energy efficiency. Additionally, demand-side measures such as the Energy Conservation Building Code (ECBC) have successfully contributed to reducing energy consumption within the infrastructure sector.

On the supply side, initiatives like the Revamped Distribution Sector Scheme (RDSS) are designed to modernize energy distribution and mitigate losses. The National Green Hydrogen Mission (NGHM) seeks to reduce dependency on energy imports while enhancing domestic production capabilities. Furthermore, renewable energy (RE) targets and initiatives, such as the ambition to achieve 175 GW of RE capacity and the Pradhan Mantri Kisan Urja Suraksha Evam Utthaan Mahabhiyan (PM KUSUM), are driving the adoption of clean energy solutions. Collectively, these strategies represent a comprehensive approach to addressing India's energy challenges, as illustrated in Figure 1

Figure 1.



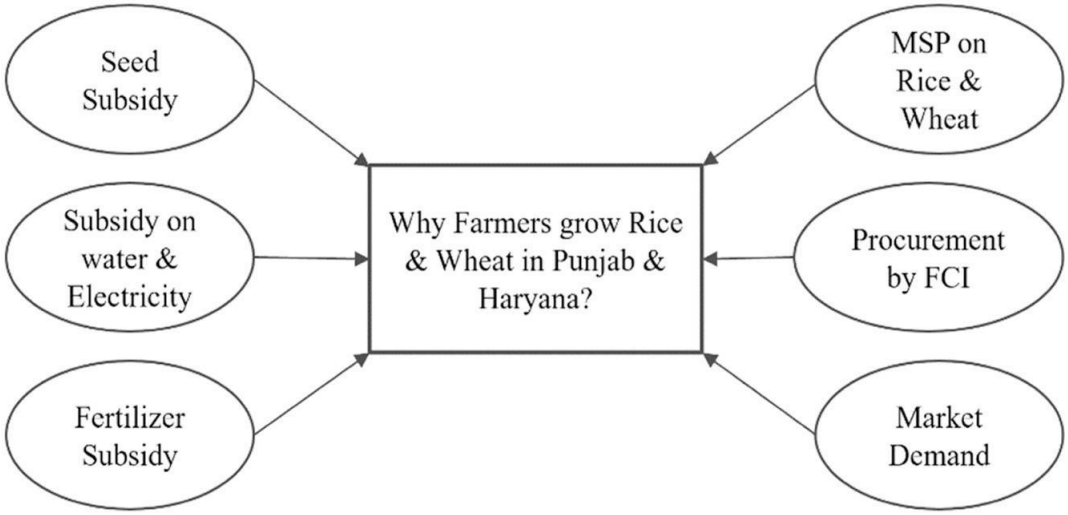
The Government of India (GOI) is working towards ramping up green hydrogen production to 5 million metric tons by the year 2030, aiming for it to make up 94% of total hydrogen output—around 28 million tons—by 2050. This strategic transition positions India as a potential frontrunner in sustainable energy, with the promise of job creation and financial growth opportunities.

Green hydrogen brings numerous benefits, particularly by complementing renewable energy (RE) production as an effective energy storage solution. It addresses the challenges of intermittent RE generation, minimizes pollution associated with resource extraction and usage, and can serve as a feedstock for traditional industries that generate emissions, such as chemicals, refineries, and metallurgy. When compared to conventional energy storage technologies, green hydrogen is more energy-dense, portable, and easier to distribute, proving to be a favorable alternative to batteries and other methods like pumped storage or melted sand energy systems. Although the effectiveness of these policies is still under evaluation, they resonate with India's ambitious target of achieving carbon neutrality by 2070, highlighting the importance of investing in research and development to enhance green hydrogen capacities and facilitate RE integration.

In an effort to achieve food self-sufficiency, the Indian government implemented a comprehensive irrigation system and introduced minimum support prices (MSP) for key

staples like rice and wheat in the late 1960s. This initiative aimed to motivate farmers to shift their cropping practices towards increasing the production of these essential grains. While these policies initially satisfied the country's immediate food demands, their long-term effects have raised concerns, particularly regarding sustainability. Collectively, these strategies represent a comprehensive approach to addressing India's energy challenges, as illustrated in Figure 2.

Figure 2.



V. Conscientious organizational culture encourages sustainable production

A variety of services exist that can help reduce the natural resource intensity associated with office work. These services include:

- Flexible office space utilization
- Rental options for furniture and equipment
- Outsourcing specific activities, such as copying
- Utilizing mainframe computer systems along with internet updates and document management services
- Energy-saving initiatives and waste management consultations
- Car-sharing programs
- Implementing telework and teleconferencing solutions

These options can significantly contribute to sustainable office practices.

VI. Requisite changes to promote sustainable agricultural policies

The agricultural landscape in India is predominantly reliant on chemical farming methods, with

over 90% of farmland utilizing these approaches. Nonetheless, there has been a noticeable uptick in the adoption of sustainable agricultural practices in recent years. For the future viability of agriculture and food production in India, widespread implementation of these sustainable methods will be crucial. Currently, however, government policies and incentives continue to favor chemical-based farming. For instance, of the total agricultural budget amounting to ₹1,250 billion— which includes allocations for agricultural education and research—only a small fraction, ₹4.6 billion, is earmarked for supporting natural farming techniques. To address the influence of the present policy framework on cropping patterns and to encourage a transition toward more sustainable practices, there is an urgent need for a fundamental reallocation of funding and a shift in policy priorities. Below are several policy mechanisms recommended to facilitate this transition toward sustainable agriculture.

(A) Sustainable agricultural practices

The Council on Energy, Environment and Water (CEEW) has undertaken comprehensive field studies to explore sustainable agricultural practices (SAPs) being employed throughout the country. Their research has identified 30 distinct SAPs, assessing their effects on key factors such as crop yield, water consumption, greenhouse gas emissions, biodiversity, and health outcomes. Various other studies have also analyzed practices including Organic Farming, Conservation Agriculture, Agroforestry, and Precision Farming, revealing a diverse array of benefits from a triple-bottom-line approach.

CEEW notes that many of these SAPs encourage crop and food diversity through methods such as intercropping, mixed cropping, and crop rotation, as well as agroforestry. This diversification of food and income sources holds significant promise for enhancing farmers' food security and improving nutritional outcomes, thereby offering a potential solution to reduce malnutrition in India. However, the transition to these practices is not without challenges, as they often require substantial knowledge and labor. Encouragingly, many farmers experiencing the adverse effects of chemical-intensive farming are open to exploring SAP alternatives. This willingness presents a valuable opportunity for government and non-governmental organizations to implement interventions in areas facing soil degradation and salinity due to excessive chemical use.

While several factors have contributed positively to the adoption of alternative-fuel vehicles, the overall growth in this area has been sluggish. It is anticipated that fossil- fuel vehicles will continue to hold a significant market share for the next 10 to 15 years. The Government's initiative in 2016 to transition from BS-IV (Bharat Stage IV) to BS-VI (Bharat Stage VI)

emission standards by 2020 was a vital step towards reducing tailpipe emissions from internal combustion engine (ICE) vehicles through technological advancements. To achieve meaningful decarbonization of the transport sector and maximize the benefits of green vehicles, a similar level of commitment and initiative is essential.

Policies aimed at improving fuel economy and promoting alternative fuels significantly influence the road transport system. Despite numerous attempts to implement initiatives like the Ethanol Blending Programme (EBP) and the National Biodiesel Mission (NBM), progress was limited. In response, the government introduced the National Policy on Biofuels, which called for a phased execution of the EBP. However, by the end of 2017, the actual blending fell short of the targets, leading to the extension of the minimum 20% blending requirement to 2030, later revised to 2025−2026. Key challenges included inadequate production capacity and the absence of standardized blending procedures.

(B) Proposed framework for policy direction

The proposed framework for managing India's energy transition focuses on aligning the nation's sustainability goals with the needs of its citizens. This framework categorizes its focus areas into four key segments.

A critical step for India is the implementation of a cap-and-trade system targeting energy-intensive sectors. This approach aims to foster discipline within industries, stimulate private investments in decarbonization technologies, and reduce emissions while simultaneously creating job opportunities. Coupled with this, enhancing the integration of renewable energy sources into the grid is essential, alongside providing incentives for Distribution Companies (DISCOMs) to promote user adoption of these technologies.

Moreover, it is vital for the government to invest in efficient energy consumption and storage systems, utilizing market-based pricing mechanisms. This strategy is designed to maintain grid stability and maximize renewable power generation. Although there may be short-term increases in electricity prices, these collective actions are poised to yield significant emissions reductions and potentially lead to substantial long-term savings.

(C) Building closed-loop supply chains

To develop effective closed-loop systems, it's essential to construct a policy framework that seamlessly connects the three sectors involved. Initially, it's crucial to motivate manufacturers of agricultural machinery and equipment to create vehicles and tools that utilize renewable energy sources, such as solar power and biofuels. Following this, farmers should be incentivized to produce the necessary biofuels locally, using resources readily available to

them, such as biomass and agricultural residues like paddy stubble. This transition is not only beneficial for reducing operational costs for farmers but also offers significant environmental advantages. By minimizing air pollution typically linked to conventional diesel machinery and discouraging the detrimental practice of burning crop residues, the overall well-being of nearby communities is improved. Furthermore, this approach encourages farmers to transform agricultural waste into biofuels, effectively completing the cycle of waste management.

(D) Redesigning farm subsidy policies

India stands to gain significantly from its energy transition, particularly through strategic financing avenues that can drive job creation and foster more equitable rural development. A pertinent example is the PM-KUSUM Yojana, which advocates for solar electricity generation to assist in agricultural water pumping. By phasing out subsidies for free electricity—which tend to fuel irresponsible consumption—India can implement a system where farmers are compensated for feeding surplus solar energy back into the grid. This shift could lead to enhanced efficiency and effectiveness in electricity utilization.

The benefits of this model are manifold: it can lower government expenditure on subsidies, reduce fossil fuel emissions with corresponding public health improvements, and increase farmers' revenue. Furthermore, it is imperative to reform existing agricultural subsidy programs and reallocate resources from chemical-heavy farming practices toward promoting farm mechanization and bio-fertilizers. Such actions are essential for encouraging the adoption of sustainable agricultural practices and ensuring the long-term viability of India’s rural economy.

VII. CONCLUSIONS

The industry operates as a dynamic network encompassing various sectors and sub- sectors, along with their interdependencies and interactions. The complexity of the relationships among dematerialization, decarbonization, corporate strategies, and governance policies cannot be overstated. India, as the most populous nation and a rapidly industrializing country, faces the challenge of balancing the improvement of its citizens' lives with the pursuit of sustainable development. In an effort to achieve carbon neutrality by 2070, the Government of India (GOI) has introduced policies targeting the energy, transportation, and agriculture sectors—key areas that contribute significantly to national development and greenhouse gas emissions. This study explores the GOI's policy focus in these three sectors from a triple-bottom-line perspective, proposing an integrated policy framework aimed at achieving the country's sustainability objectives.
